4) The bacteria Porphyromonas gingivalis is often found in periodontal disease and has been implicated in the development of chronic periodontitis. 

5) A study by the team investigated the role of Porphyromonas gingivalis in periodontal disease progression and found that the bacteria can cause significant inflammation in the gums.

6) Another study showed that Porphyromonas gingivalis can destroy the integrity of the dental enamel, leading to the development of cavities.

7) Researchers have also discovered that Porphyromonas gingivalis can form biofilms on the surface of the teeth, making it difficult to remove with traditional cleaning methods.

8) The bacteria Acinetobacillus actinomycetemcomitans has been found to be associated with periodontal disease and can also contribute to the development of chronic periodontitis.

9) Treponema denticola has also been implicated in periodontal disease, as it can cause damage to the periodontal ligament and bone.
